Stats 21: Homework 1

Hector Lugo Barrios

I've started the homework file for you. You'll need to fill in the rest with your answers. My encouragement is to use the keyboard shortcuts as much as possible and use the mouse as little as possible while working the Jupyter Notebook.

After you complete the homework with your answers, go to the menu and choose Kernel > Restart & Run All. Go through the document to **make sure all requested output is visible**. You will not get credit for problems where the requested output is not visible, even if the function you coded is correct.

When you are satisfied with the output, choose File > Download As ... > PDF or HTML. If you choose to save as HTML, you'll then need to "Print as PDF". Submit the PDF to Gradescope.

Again, you must make sure all requested output is visible to receive full credit.

Task 1

Create an account on GitHub.

Change your profile picture. Ideally, use photo of yourself that would be appropriate for a resume. If you are not comfortable with the idea of using a photo of yourself, use any other image that is suitable for a workplace environment.

Create a repository on GitHub (other than the forked class notes repository). Make at least two additional commits to the reposiotry and push them to GitHub.

Provide a link to your repository here.

Your Answer:

Link to your repository: https://github.com/hectorlugob/Homework1

Problem 2

An important part of programming is learning to interpret error messages and understanding what correction needs to be made.

Read and familiarize yourself with the following error messages.

Explain the error. Then duplicate each cell and correct the error. The first problem has been done for you as an example.

In [1]:

```
# A
print("Hello World"
```

```
  File "<ipython-input-1-41ea49db4490>", line 2
    print("Hello World"
                       ^
SyntaxError: unexpected EOF while parsing
```

Answer: The `print()` function is missing the closing parenthesis. This results in an unexpected EOF error.

In [21]:

```
# corrected:
print("Hello World")
```

```
Hello World
```

In [2]:

```
# B
print("Hello")
    print("Goodbye")
```

```
  File "<ipython-input-2-5488ccf53c57>", line 3
    print("Goodbye")
    ^
IndentationError: unexpected indent
```

Answer: The `print("Goodbye")` command should not be indented.

In [22]:

```
# corrected:
```

```
print("Hello")
print("Goodbye")
```

```
Hello
Goodbye
```

In [3]:

```
# C
x = 10
if x > 8
    print("x is greater than 8")
```

```
  File "<ipython-input-3-14f8f1c1ae69>", line 3
    if x > 8
           ^
SyntaxError: invalid syntax
```

Answer: The `if` statement requires `x > 8` to go inside parentheses and use `:` afterwards.

In [23]:

```
# corrected:
x = 10
if x > 8:
    print("x is greater than 8")
```

```
x is greater than 8
```

In [4]:

```
# D
if x = 10:
    print("x is equal to 10")
```

```
  File "<ipython-input-4-9a8ad4f44137>", line 2
    if x = 10:
         ^
SyntaxError: invalid syntax
```

Answer: The symbol `=` is used for assignment, while `==` is used for testing if two values are equal.

In [24]:

```
# corrected:
if x == 10:
    print("x is equal to 10")
```

```
x is equal to 10
```

In [5]:

```
# E
x = 5
if x == 5:
print("x is five")
```

```
  File "<ipython-input-5-644642793b85>", line 4
    print("x is five")
    ^
IndentationError: expected an indented block
```

Answer: We need to indent the block that we want to run inside the `if` statement

In [25]:

```
# corrected:
x = 5;
if x == 5:
    print("x is five")
```

```
x is five
```

In [6]:

```
# F
l = [1, 2, 50, 10]
l = sort(l)
```

```
---------------------------------------------------------------------------
NameError                                 Traceback (most recent call last)
<ipython-input-6-ef239315c341> in <module>
      1 # F
      2 l = [1, 2, 50, 10]
----> 3 l = sort(l)

NameError: name 'sort' is not defined
```

Answer: sort is not defined. Instead we need to use the sorted() function, which is sorts numbers of a list in ascending order by default.

In [26]:

```
# corrected
l = [1, 2, 50, 10]
l = sorted(l)
print(l)
```

```
[1, 2, 10, 50]
```

Problem 3

Use Python as a calculator. Enter the appropriate calculation in a cell and be sure the output value is visible.

A. How many seconds are there in 42 minutes 42 seconds?

In [8]:

```
ans_p3a = (42 * 60) + 42
print("There are", ans_p3a, "seconds")
```

```
There are 2562 seconds
```

B. There are 1.61 kilometers in a mile. How many miles are there in 10 kilometers?

In [9]:

```
ans_p3b = 10 / 1.61
print("There are", "%0.2f" % ans_p3b, "miles in 10 kilometers")
```

```
There are 6.21 miles in 10 kilometers
```

C. If you run a 10 kilometer race in 42 minutes 42 seconds, what is your average 1-mile pace (time to complete 1 mile in minutes and seconds)? What is your average speed in miles per hour?

In [10]:

```
velocity1 = 10 / 2562
time2 = 1.61 / velocity1
seconds_time2 = time2 % 60
minutes_time2 = time2 // 60
print("The average 1-mile pace is", "%0.2f" % minutes_time2, "minutes and", "%0.2f" % seconds_time2, "sec
conversion_factor = 2236.94
speed_in_mph = velocity1 * conversion_factor
print("The average speed in miles per hour is", "%0.2f" % speed_in_mph, "miles per hour")
```

```
The average 1-mile pace is 6.00 minutes and 52.48 seconds.
The average speed in miles per hour is 8.73 miles per hour
```

Problem 4

Write functions for the following problems.

A. The volume of a sphere with radius r is $$V = \frac{4}{3}\pi r^3$$

Write a function `sphere_volume(r)` that will accept a radius as an argument and return the volume.

- Use the function to find the volume of a sphere with radius 5.
- Use the function to find the volume of a sphere with radius 15.

In [11]:

```
# creating function:
import math
def sphere_volume(r):
    volume = (4 / 3) * math.pi * r**3
    return volume

radius5 = sphere_volume(5)
radius15 = sphere_volume(15)
print("The volume of a sphere with radius 5 is", "%0.2f" % radius5, "units cubed")
```

```
print("The volume of a sphere with radius 15 is", "%0.2f" % radius15, "units cubed")
```

```
The volume of a sphere with radius 5 is 523.60 units cubed
The volume of a sphere with radius 15 is 14137.17 units cubed
```

B. Suppose the cover price of a book is \$24.95, but bookstores get a 40\% discount. Shipping costs \\$3 for the first copy and 75 cents for each additional copy.

Write a function `wholesale_cost(books)` that accepts an argument for the number of books and will return the total cost of the books plus shipping.

- Use the function to find the total wholesale cost for 60 copies.
- Use the function to find the total wholesale cost for 10 copies.

In [12]:

```
def wholesale_cost(books):
    cover_price = books * 24.95
    discount = cover_price * 0.4
    books_price = cover_price - discount
    copies = books - 1
    shipping = 3 + (copies * 0.75)
    total = books_price + shipping
    return total

cost_60 = wholesale_cost(60)
cost_10 = wholesale_cost(10)

print("The total wholesale cost for 60 copies is $%0.2f" % cost_60)
print("The total wholesale cost for 10 copies is $%0.2f" % cost_10)
```

```
The total wholesale cost for 60 copies is $945.45
The total wholesale cost for 10 copies is $159.45
```

C. A person runs several miles. The first and last miles are run at an 'easy' pace. Other than the first and last miles, the other miles are at a faster pace.

Write a function `run_time(miles, warm_pace, fast_pace)` to calculate the time the runner will take. The function accepts three input arguments: how many miles the runner travels (minimum value is 2), the warm-up and cool-down pace, the fast pace. The function will print the time in the format minutes:seconds, and will return a tuple of values: (minutes, seconds)

Use the function to find the time to run a total of 5 miles. The warm-up pace is 8:15 per mile. The speed pace is 7:12 per mile.

Call the function using: `run_time(miles = 5, warm_pace = 495, fast_pace = 432)`

In [ ]:

```
def run_time(miles, warm_pace, fast_pace):
    ##not completed
```

Another important skill is to be able to read

Now look up the function str.split() at https://docs.python.org/3/library/stdtypes.html#str.split

Adjust the function so that the call can be made with minutes and seconds:

```
run_time(miles = 5, warm_pace = "8:15", fast_pace = "7:12")
```

In [ ]:

```
## not completed
```

Problem 5

Use `import math` to gain access to the math library.

Create a function `polar(real, imaginary)` that will return the polar coordinates of a complex number.

The input arguments are the real and imaginary components of a complex number. The function will return a tuple of values: the value of the radius `r` and the angle `theta`.

For a refresher, see: https://ptolemy.berkeley.edu/eecs20/sidebars/complex/polar.html

Show the results for the following complex numbers:

- 1 + i
- -2 - 3i
- 4 + 2i

In [13]:

```
import math
def polar(real, imaginary):
    r = math.sqrt(real**2 + imaginary**2)
    sine_theta = imaginary / r
    theta = math.asin(sine_theta)
    return r, theta

first = polar(1, 1)
second = polar(-2, -3)
third = polar(4, 2)

print("The complex number 1 + i is expressed as", first, "in polar coordinates")
print("The complex number -2 - 3i is expressed as", second, "in polar coordinates")
print("The complex number 4 + 2i is expressed as", third, "in polar coordinates")
```

```
The complex number 1 + i is expressed as (1.4142135623730951, 0.7853981633974482) in polar coordinates
The complex number -2 - 3i is expressed as (3.605551275463989, -0.9827937232473292) in polar coordinates
The complex number 4 + 2i is expressed as (4.47213595499958, 0.4636476090008061) in polar coordinates
```

Problem 6

Define a function called `insert_into(listname, index, iterable)` . It will accept three arguments, a currently existing list, an index, and another list/tuple that will be inserted at the index position.

Python's built-in function, `list.insert()` can only insert one object.

In [14]:

```
# write your code here
def insert_into(listname, index, iterable):
    left_side = listname[0:index]
    right_side = listname[index:len(listname)]
    new_list = left_side + iterable + right_side
    return new_list
```

In [15]:

```
# do not modify. We will check this result for grading
l = [0,'a','b','c',4,5,6]
i = ['hello', 'there']
insert_into(l, 3, i)
```

Out[15]:

```
[0, 'a', 'b', 'hello', 'there', 'c', 4, 5, 6]
```

Problem 7

Define a function called `first_equals_last(listname)`

It will accept a list as an argument. It will return `True` if the first and last elements are equal and the if the list has a length greater than 1. It will return False for all other cases.

In [16]:

```
# write your function here
def first_equals_last(listname):
    is_equal = False
    if (len(listname) >= 2) & (listname[0] == listname[-1]):
        is_equal = True
    return is_equal
```

In [17]:

```
# do not modify. We will check this result for grading
a = [1,2,3]
first_equals_last(a)
```

Out[17]:

```
False
```

In [18]:

```
# do not modify. We will check this result for grading
b = ['hello','goodbye','hello']
```

```
first_equals_last(b)
```

Out[18]:

```
True
```

In [19]:

```
# do not modify. We will check this result for grading
c  = [1,2,3,'1']
first_equals_last(c)
```

Out[19]:

```
False
```

In [20]:

```
# do not modify. We will check this result for grading
d = [[1,2],[3,2],[1,2]]
first_equals_last(d)
```

Out[20]:

```
True
```
